

Secondary Distribution Box in Mozambique

AI Overview

A secondary distribution box (SDB) is an electrical panel that receives power from a primary distribution source and distributes it to specific buildings, floors, or equipment, ensuring safe and reliable delivery of electricity at lower voltages.

Definition and Function A secondary distribution box is also known as a sub-distribution box. It receives electrical power from the primary distribution box or transformer and distributes it to end-use areas such as individual buildings, floors, or industrial equipment. In Mozambique, as in other countries, it typically operates at low voltage levels below 1 kV, often around 0.4 kV, suitable for residential, commercial, and light industrial applications. The main purposes of a secondary distribution box are:

- Power distribution:** It channels electricity from the main transformer or primary distribution box to specific areas or loads.
- Safety and protection:** Equipped with three-phase circuit breakers, isolating switches, and sometimes residual current devices (RCDs), it protects circuits and connected equipment from overloads and faults.
- Local control:** Allows operators to manage and isolate power for specific sections without affecting the entire system.

Typical Equipment Secondary distribution boxes usually contain:

- Three-phase circuit breakers for load protection
- Terminal blocks for custom wiring and connections
- Powder-coated enclosures for durability and outdoor use
- Snap-on extender cables to connect to branch circuits or floor modules

Role in Mozambique's Electrical System In Mozambique, secondary distribution boxes are part of the medium- to low-voltage distribution network, bridging the gap between the main transformer or primary distribution box and the end-user equipment. They are essential in urban and industrial areas where electricity must be safely and efficiently distributed to multip...
