

The fan in the network cabinet is not spinning

AI Overview

A network cabinet fan that isn't spinning is usually caused by power issues, connection problems, dust buildup, or a faulty fan motor, and can often be resolved through systematic troubleshooting. Check Power and Connections Ensure the fan is properly connected to the power source or fan controller. Loose or disconnected cables are a common cause of non-spinning fans. If the fan is connected via a Molex or 3-pin/4-pin header, verify that the connectors are secure and correctly oriented. Testing the fan on a different power source or header can help determine if the issue is with the fan or the power supply/controller itself. Inspect BIOS or Controller Settings Some fans are controlled via BIOS or a dedicated fan controller. Check that the fan is enabled and configured correctly. For 3-pin fans on a 4-pin header, you may need to switch the header from PWM to voltage-regulated mode in BIOS. If the fan is connected to a hub or controller, ensure the controller is powered on and functioning. Clean and Lubricate the Fan Dust and debris can jam the fan blades, preventing rotation. Use compressed air to clean the fan thoroughly. For fans with oil-based bearings, a drop of lubricating oil on the bearing can restore smooth spinning, but avoid getting oil on the blades or motor housing. Test the Fan If possible, test the fan independently by connecting it directly to a known working power source. If it spins, the problem may be with the fan hub, controller, or motherboard header. If it still does not spin, the fan motor may be defective and require replacement. Additional Considerations Ensure no cables or obstructions are physically blocking the fan blades. Verify that the power supply can provide sufficient voltage for the fan, especially if the fan light works but the motor does not. If the fan is part of a prebuilt system with RGB controls, check that the fan motor has not been disabled via the r...
